

with the last whorl much expanded and convex, and projecting more in proportion than all the foregoing. Aperture quadrangular, somewhat angled in front; columella straight, reflected to the right; umbilicus broad.

Colour.—Milky.

Dimensions.—2 to 2.5 mm. in height, about 1.5 mm. in maximum diameter.

Operculum approximately oval, with an almost straight columellar margin, and with a spiral portion measuring barely two-fifths of the entire length.

The animal exhibits a small lobe on the dorsal margin of each fin.

Habitat.—Cape Horn (Souleyet).

From its discovery by Souleyet this species was not reobserved until the Challenger Expedition. Jeffreys¹ follows Vérany in noting the coast of Piedmont as a locality of *Spirialis australis*, and this has been repeated without question by various authors.² The statement is, however, entirely erroneous, and has in all probability reference to *Limacina trochiformis*.

The specimens collected by the Challenger show that this species has a somewhat wide distribution round the South Pole, where it occupies, along with *Limacina antarctica*, a position analogous to that of *Limacina retroversa* and *Limacina helicina* in the north.

Challenger Specimens.—Living.

Station 146, December 29, 1873; Marion Island to Crozets; lat. 46° 46' S., long. 45° 31' E.

Station 149, January 9, 1874; at Kerguelen Island; lat. 49° 8' S., long. 70° 12' E.

Station 150, February 2, 1874; Heard Island; lat. 52° 4' S., long. 71° 22' E.

Between Stations 154 and 155, February 21, 1874; in vicinity of Antarctic Ice; lat. 63° 30' S., long. 89° 8' E.

Observations.—Boas³ has expressed hesitation in regard to the possible specific identity of *Limacina australis*, *Limacina retroversa*, and *Limacina trochiformis*. They are, however, as we shall see, three very distinct forms.

In the first place, as regards *Limacina trochiformis*, it belongs along with *Limacina bulimoides* to a special group of *Limacinæ* quite different from that to which *Limacina australis* and *Limacina retroversa* are to be referred. It is characterised by the presence of a shell with oval, rounded aperture, with the columellar margin reflected to the left, and with a very narrow umbilicus. In *Limacina bulimoides* and *Limacina trochiformis* also the animal is without any lobe on the fin. In *Limacina australis*, on the other hand, the opening of the shell is quadrangular, with the columellar margin reflected to the right, with a very broad umbilicus, and a tentacle-like lobe on the dorsal margin of the
